Tibialis anterior muscle is active through both stance and swing phases in running. It is active for about 73% of the cycle (compared to 54% when walking). The swing phase when running, is 62% of the total gait cycle, compared to 40% when walking, so TA is considerably more active when running.

Running - 1st Edition

Energy cost of running (C_r) linearly increases with positive slope but C_r of DR decreases until a minimum slope is reached at -20 %, after which C_r increases again. The effects of slope on biomechanics, muscle contraction patterns and physiological responses have important implications for injury prevention and success of athletes engaged in graded running competitions.

Background: Previous studies have shown that changing acutely from shod to barefoot running induces several changes to running biomechanics, such as altered ankle kinematics, reduced ground-reaction forces, and reduced loading rates. However, uncertainty exists whether these effects still exist after a short period of barefoot running habituation.

Running: Biomechanics and Exercise Physiology in Practice ...

Both genetic and adaptive factors affect an athlete's efficiency. This article breaks each phase of a distant runner's performance into its biomechanical components, looking at common errors that affect the athlete's form. The goal is a better understanding of what it takes to improve running economy to minimize energy expenditure over long distances.
